Generative Models and Quality Constraints for Anomaly Detection : Application to Industrial and Medical Images

Arnaud Bougaham[1], Benoît Frénay[1] and Isabelle Linden[2]

[1]Faculty of Computer Science, NaDI Institute, University of Namur, Rue Grandgagnage 21, Namur, 5000, Belgium.
[2]Department of Management Sciences, NaDI Institute, University of Namur, Rempart de la Vierge 8, Namur, 5000, Belgium.

Context

Advanced anomaly detection :

- Crucial quality control step
- Important part of Industry 4.0 opportunities

Traditional algorithms suffer from practical drawbacks :

- High false positive rate
- Limited Regions of Inspection

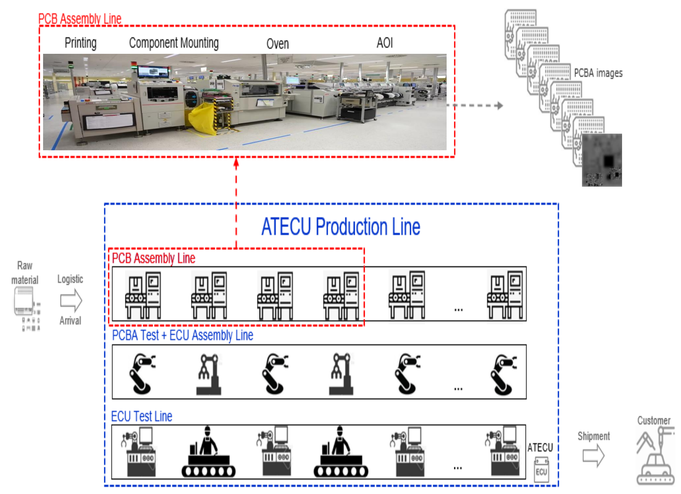

Figure 1: PCBA Manufacturing Process Flow

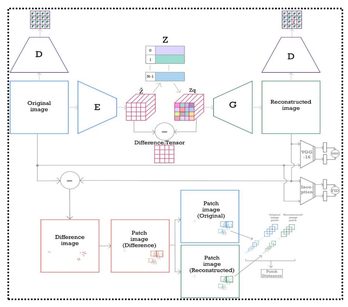
Research Questions

- What are the best deep learning techniques to detect anomalies that exist in real-world industrial datasets? (unsupervised learning, high-resolution images, imbalanced datasets, etc.)
- How to integrate the business constraints (full TPR, acceptable inference time, worker interactions, explainable decisions, etc.) into a binary normal/abnormal classification algorithm?

Methods & Results

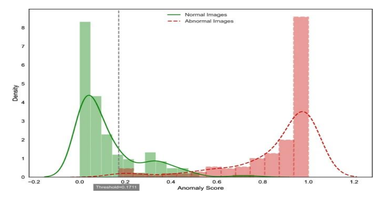
[1][2] VQGanoDIP = VQGAN Reconstruction + Metrics Classification for Anomaly Detection

- Train an Encoder, a Codebook, a Generator and a Discriminator through a GAN framework, in an autoencoder architecture
- Get statistics on the residual image and in the networks losses to quantify how the image is different from the normality
- Train a binary extra tree classifier to discriminate between normal and abnormal products



$$\mathcal{Q}^* = \underset{E,G,Z}{argmin}\ \underset{D}{max}\ \mathop{\mathbb{E}}_{x\sim p(x)}\left[\mathcal{L}_{VQ}(E,G,Z) + \lambda \mathcal{L}_{GAN}(\{E,G,Z\},D)\right]$$

$$\begin{cases} \mathcal{L}_{GAN}(\{E,G,Z\},D) = \left[\log D(x) + \log\left(1 - D\left(G\left(Z(E(x))\right)\right)\right)\right], \\ \mathcal{L}_{VQ}(E,G,Z) = \left\|x - G\left(Z(E(x))\right)\right\|^2 + \|sg[E(x)] - z_q\|_2^2 + \|sg[z_q] - E(x)\|_2^2, \\ \lambda = \frac{\nabla_{GL}[\mathcal{L}_{rec}(\{E,G,Z\})]}{\nabla_{GL}[\mathcal{L}_{GAN}(\{E,G,Z\},D)]+\delta}, \end{cases}$$



Dataset (Classifier)	Accuracy(%)↑ STD	ZFN
PCBA (ET)	95.69	87.93
Cable (XGBoost)	76.82	57.94
Carpet (LR)	85.6	50.21
Grid (LR)	95.98	85.43
Hazelnut (LGBM)	98.95	98.25
Leather (XGBoost)	92.17	90.43
Screw (ADA)	93	83.67
Transistor (LGBM)	88.7	49.15
Zipper (LGBM)	92.55	81.57

Quality: 37%
False Positives saved

Performance: 72%
Inspection time saved

Future Works

1st part of the approach is an image reconstruction through a GAN model. To optimally reconstruct the input image (and focus on the real anomalies), other generative model architectures will be compared.

- ViT in GAN : Replace all or parts of the CNNs by Visual Transformers.

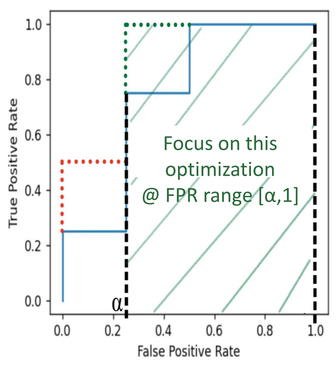
CNNs of GAN → Vision Transformer

- Diffusion Model : Consider an autoencoder with latent diffusion process.

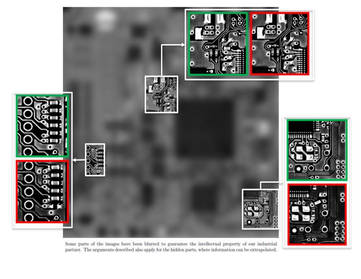
GAN in autoencoder → Diffusion Model

2nd part of the approach is the metrics classification. A customized function loss is being designed to reflect a full sensitivity constraint.

- A partial AUC [4] is formulated, so that only the Full TPR part is targeted while minimizing the FPR.
- This pAUC is then approximated by a Wilcoxon-Mann-Whitney Statistic loss [5], well fitted for a neural network classifier.



$$\mathcal{L}_{WMW_{approx}\ pAUC} = \begin{cases} \frac{1}{S^+ S_\alpha^-} \sum_{i=1}^{S^+} \sum_{j=1}^{S_\alpha^-} (s_i^+ + \gamma - s_j^-)^2 & \text{if } s_i^+ + \gamma < s_j^- \\ 0 & \text{otherwise} \end{cases}$$



Some parts of the images have been blurred to guarantee the intellectual property of our industrial partner. The arguments described also apply for the hidden parts, where information can be extrapolated.

On-site industrial integration is performed, highly focused on the worker habits, the inference time and quality constraints.

Another medical use case is being studied, on activation detection during alternative rest/stimulation phases for fPET sinograms.
